NOTE: THIS VERSION OF THE SUPPORTING APPENDIX SUPERCEDES THE VERSION ORIGINALLY PUBLISHED.

While helping out with a replication study, we recently discovered some mistakes in the R code used to generate the results. These mistakes related to the handling of the index labels for clustering standard errors in some of the models. Relatedly, we also made some adjustments to the way groups were defined for the persistence and group-based regressions, and, in some cases, to the censoring procedure for interval regression. Fixing this coding generally yielded small *decreases* in the reported standard errors. Hence, some of our results, as reported, were unduly conservative. Most of the results are unchanged.

However, there are changes in three substantive interpretations that should be noted:

1. In **Table S1d** we now report that the effect of alter's alter's alter's alter's contribution on ego's contribution is significant for the ordinary public goods game (we previously reported that it was not significant). This suggests that donation cascades may actually extend up to 4 degrees of separation in public goods games (in contrast to the 2 degrees result we originally reported).
2. In **Tables S2a-d** we now report that the effect of alter's contribution on ego's contribution persists only up to two periods (Tables S2a-S2d), and not more than that. See corrected Fig. 4 below. In other words, if A treats B kindly, then B will go on to be kind to C in the next period and also B will go on to be kind to D in the period after that. This persistence across time is, as noted in the paper, a separate matter than the spread across individuals (where A is kind to B and then B is kind to C and then C is kind to D), which is the main focus of the paper.
3. In **Table S5b** we now report that the effect of Alter's Alter's Received Punishment on Ego's Contribution is significant (we previously reported that it was not significant). This suggests that punishment might, in fact, spur cooperation cascades.

In Tables S1a-S1d, we show regression results used to estimate the total effects shown in Fig. 3 of the main text. The right-most points (4 degrees of separation) in Fig. 3 are incorrect in the published text—they should be 0.27 (95% C.I. 0.05 to 0.49) for the public goods game and 0.07 (95% C.I. -0.05 to 0.23) for the public goods game with punishment.

In Tables S1a and S2a-S2d, we show regression results used to estimate the effects shown in the top two panels of Fig. 4 of the main text. In Tables S1b and S3a-S3c, we show regression results used to estimate the effects shown in the bottom two panels of Fig. 4 of the main text. The corrected figure is shown on the following page.

In Tables S4a-b we show regression results used to estimate the mediation effect of alter's contribution on the relationship between alter's contribution and ego's contribution. What this mediation analysis shows is that, as we theorized, the total effect of alter's contribution on ego disappears when we control for the effect of alter on ego. This is a classic mediation result. Suppose that X affects M and M affects Y , then X can affect Y via its influence on M . In this case X is the alter's contribution, M is the mediator, and Y is the ego. To test whether or not a mediation effect is present requires two regressions, (1) regress M on X (first model in Tables S4a and S4b), and (2) regress Y on M and X (second model in Tables S4a and S4b). According to Sobel (1982), M is a mediator if the product of the coefficients on X in the first regression and M in the second regression is

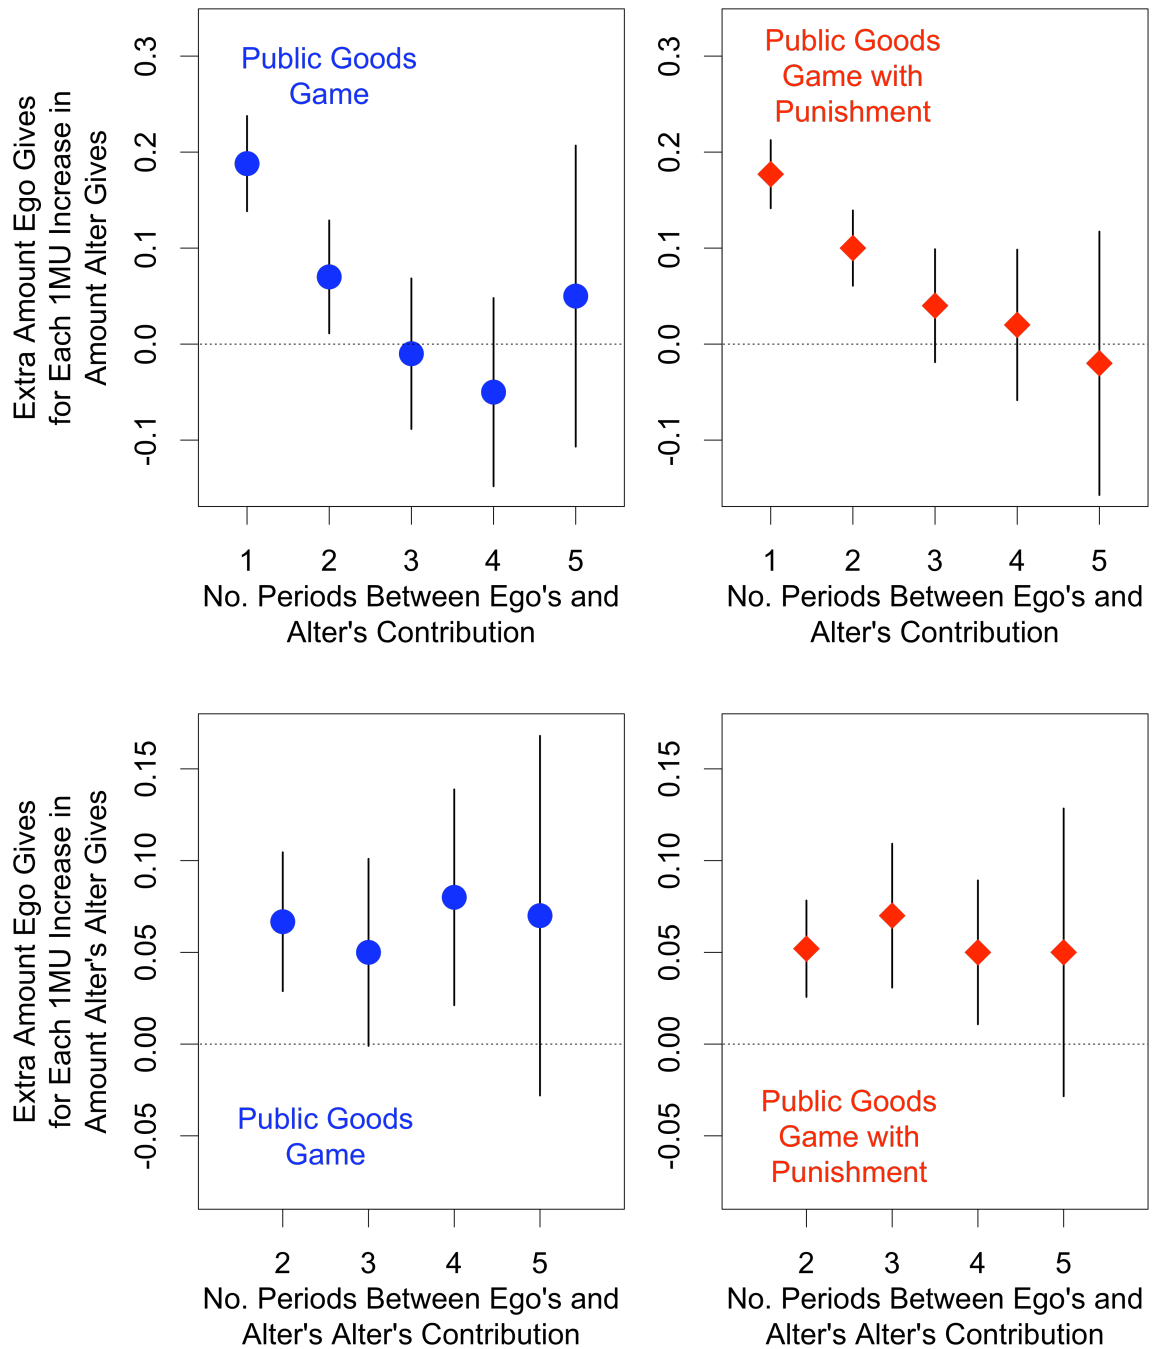

Figure 4 (Corrected). The total effect of alter's giving on ego's giving persists beyond the initial period. (Upper) Alter significantly influences ego's behavior up to two periods later in the public goods game (Left) and the public goods game with punishment (Right). (Lower) Alter's alter (two degrees of separation) significantly influences ego's behavior up to four periods later in the public goods game (Left) and the public goods game with punishment (Right). Estimates are from interval regressions, controlling for multiple observations of the same ego, multiple observations of the same alter, the ego's initial contribution in the period in which alter's (or alter's alter's) contribution was made, and period fixed effects. Vertical bars show 95% confidence intervals.

significant ($p < 0.001$ in both the public goods game and the public goods game with punishment). Furthermore, we note that the effect of alter's alter is no longer significant in the second regression, suggesting that X has no independent influence on Y . In other words, alter's alter's effect on ego results from alter's alter's effect on alter and then alter's effect on ego. In Tables S5a-b we show regression results used to estimate the effect of alter's alter's and alter's alter's alter's punishment behavior on ego's contribution.

In Tables S6a and S6b, we demonstrate that egos are not more influenced by "selfish" behavior than by "generous" behavior. In other words, alter's effect on ego does not vary for high and low contributions (increasing alter's contribution from 0MUs and 10MUs has the same effect on ego as increasing from 10MUs to 20MUs). In Table S6a, we use the *median contribution across groups and rounds* as a point of reference to divide high and low contributions, and in Table S6b we use the *ego's own contribution* as a point of reference.

In Table S7a and S7b, we explore the possibility that groups rather than specific individuals influence ego's behavior. In Table S7a, we show that alter significantly influences ego even when we include the contributions made by the other two members of the group as a control. In Table S7b, we test the influence of the other two member's contributions on alter's effect on ego by adding an interaction term to the model. The effect is significant in the public goods game but not in the public goods game with punishment, and in both cases the effect size is negligible. When other members of the group increase their contributions, it decreases the influence of alter on ego by 0.004. If we hold other group members' contributions constant at 10 each, the model suggests that an additional MU contributed by alter increases the contribution of ego in the next period by 0.160MUs, but if we increase other group members' contributions by 1MU, then an additional MU contributed by alter increases the contribution of ego in the next

period by 0.156MUs. And even when others contribute maximally, alter's effect on ego remains significant ($p=0.04$).

In Table S8, we show that punishment behavior does not spread from alters to ego. In Tables S9a-S9c, we study the effect of groups of alters rather than individual alters. These models show that the sum total of contributions by all alters in the group significantly influence ego's contribution up to two degrees of separation in the normal public goods game and up to three degrees of separation in the public goods game with punishment, mirroring the individual-level results in Tables S1a-S1c. We present these results to show that the effects are robust to specification.

In Tables S10a and S10b, we add additional lags to the model of alter's influence on ego and alter's alter's influence on ego. Note that the model results reported in Table S10 indicate that alter and alter's alter significantly influence ego in both the public goods game and the public goods game with punishment, and the effect sizes are nearly identical. However, the cost of these models is dramatically reduced sample size (and therefore the efficiency of estimation) since each additional lag eliminates one period of observations.

Finally, in Table S11, we add 235 fixed effects for each unique subject (except the baseline subject, since a constant is in the model). This method has the advantage of controlling for all fixed differences between individuals and/or sessions, but it is well known to generate coefficients that are biased towards zero, especially when the number of fixed effects is large, as it is here. In spite of the conservative nature of this technique, we find that alter continues to have large and significant effects on ego as in the models without fixed effects.

<i>Null Log Likelihood</i>	-19553			-20970			-19553		
<i>N</i>	8316			8316			8316		

Interval regression models of ego and alter contributions, controlling for multiple observations of the same ego and multiple observations of the same alter using Huber-White sandwich standard errors. The results in the first model show that the size of the total effect of alter's alter on ego is 0.07 (95% C.I. 0.03 to 0.10). We can use the results of the second and third model to calculate the size of the indirect effect of alter's alter on ego that is mediated by alter, which is 0.07 (95% C.I. 0.05 to 0.09). We note that, as theorized, the effect of alter's alter is no longer significant when we control for alter. These results together mean we cannot reject the hypothesis that the total effect of alter's alter on ego is mediated by the effect of alter's alter on alter.

Interval regression models of ego and alter contributions, controlling for multiple observations of the same ego and multiple observations of the same alter using Huber-White sandwich standard errors. The results in the first model show that the size of the total effect of alter's alter on ego is 0.05 (95% C.I. 0.03 to 0.08). We can use the results of the second and third model to calculate the size of the indirect effect of alter's alter on ego that is mediated by alter, which is 0.03 (95% C.I. 0.02 to 0.05). We note that, as theorized, the effect of alter's alter is no longer significant when we control for alter. These results together mean we cannot reject the hypothesis that the total effect of alter's alter on ego is mediated by the effect of alter's alter on alter.

Table S5a: Effect of Alter's Received Punishment on Ego's Contribution Two Rounds Later

	<i>Dependent Variable:</i>		
	<i>Ego's Contribution in Period t</i>		
	<i>Coef.</i>	<i>S.E.</i>	<i>p</i>
<i>Punishment Rec'd by Alter in Period $t - 2$</i>	0.13	0.05	0.02
<i>Alter's Contribution in Period $t - 2$</i>	0.18	0.03	0.00
<i>Punishment Rec'd by Ego in Period $t - 2$</i>	0.45	0.07	0.00
<i>Ego's Contribution in Period $t - 2$</i>	0.86	0.03	0.00
<i>Period 4</i>	-1.14	0.33	0.00
